HW3 problem 2

March 22, 2026

From testing a buffer size of 1-10, the results are shown above. The relationship is inversely proportional as expected. As the number of bytes increases, the time taken decreases. It is worth noting that 8 bytes read at a time is the lowest time taken even though 9 and 10 bytes should in theory be faster, but took longer.

The graph looks logarithmic especially when only plotting powers of 2. The results are very distinct from 1-8 and begin to provide less and less time differences as the number of bytes increases upwards of 64 and beyond. The curve is steep at lower bytes and flat at higher bytes.
